We present a tomographic reconstruction procedure that exploits the symmetry of the SU(1,1) group existing in some physical systems. The tomographic algorithm is derived analytically and the convergence of the procedure is tested on Monte Carlo simulated data.

I. INTRODUCTION

Optical homodyne tomography is a well-established method for measuring the quantum state of the radiation field [1–4], and, more generally, for estimating the expectation value of arbitrary observables of the field [5] also for any number of field modes [6]. The success of optical homodyne tomography has stimulated the design of state-reconstruction procedures in other fields, such as in atomic [7], molecular [8], and ion-trap [9] physics. Homodyne tomography allows the estimation of the ensemble average of any field operator—including the matrix elements of the quantum state—by averaging special functions of the field quadratures with varying phase. These are the analogs of all linear combinations of position and momentum of a harmonic oscillator. The set of field quadratures is an example of a quorum of observables, namely, a “complete” set of noncommuting observables which are sufficient for determining the quantum state of the system. With the only exception of the method of Ref. [10]—in which the tomographic reconstruction is achieved through measurement of the photon number probability of the “displaced” state—no other quorum, different from the set of field quadratures, has been considered in the optical domain (the “self-homodyne” tomography [11] is also based on quadrature measurements, although not via homodyning). Indeed, a non-quadrature-based tomographic method would be very interesting in comparison with homodyne tomography, in order to compare the efficiency of different quorums, and to analyze the role played by these in the tomographic reconstruction.

In this paper a totally different tomographic reconstruction procedure is proposed. It is based on the general theory given in Refs. [12–14]. This reconstruction exploits the SU(1,1) group symmetry [15] and its infinite dimensional unitary irreducible representations in order to derive the pattern functions. Once these have been obtained, the tomographic procedure can be derived immediately, since it simply consists in averaging the pattern functions over the experimental results.

To test the method, we present numerical results for a set of computer-simulated state-reconstruction experiments, corresponding to the reconstruction of different quantum states. As we will see, there is always an excellent quantitative agreement between theoretical and experimental matrix elements, with unbiased statistical errors that can be arbitrarily reduced for increasing number of data.

II. GENERAL TOMOGRAPHY

In this section we briefly review the general quantum tomography method of Refs. [13,14]. The purpose of quantum tomography is to reconstruct the expectation value of any operator $A$ acting on the system Hilbert space $\mathcal{H}$, using only measurement outcomes of a set, called a quorum, of observables $C(x)$ [i.e., $C(x)$ for fixed $x$ has spectral orthonormal resolution]. By measuring $C(x)$ for various $x$, it is possible to reconstruct the expectation value of $A$ starting from the following resolution of the identity on the operator space:

$$A = \int d\mu(x) \text{Tr}(AB^+(x))C(x),$$

where the set $B(x)$ is the dual set of $C(x)$ under the Hilbert-Schmidt scalar product, and $\mu(x)$ denotes a suitable measure. In general $x = (x_1, x_2, \ldots)$ denotes a vector of parameters, with $x_i$ either continuous or discrete, and the notation $\int d\mu(x)$ denotes multiple integrals/sums.

The dual couple $B(x)$ and $C(x)$ satisfy the orthogonality relation

$$\delta_{mn}\delta_{kl} = \int d\mu(x) \langle m|B^+(x)|n\rangle \langle l|C(x)|k\rangle,$$

which, for $\{|m\}\}$ denoting an orthonormal basis of $\mathcal{H}$, is just a restatement of the tomography identity (1). Alternatively, if $\{|m\}$ spans only a subspace of $\mathcal{H}$, then Eq. (1) will hold
only for operators restricted to this subspace. As we will see, this is the case of the SU(1,1) tomography in some of its physical realizations.

Once a dual couple $B(x)$ and $C(x)$ has been found, one can obtain the expectation value of an arbitrary operator $A$, by taking the expectation of both members of Eq. (1), i.e.,

$$
\langle A \rangle = \sum_n \int d\mu(x)p_n(x)\lambda_n(x)\text{Tr}[B^\dagger(x)A],
$$

(3)

where $p_n(x)$ is the probability of obtaining the $n$th eigenvalue $\lambda_n(x)$ when measuring $C(x)$, i.e., $p_n(x) = \langle n|\Psi|x \rangle$ (with $\Psi$ the density matrix of the system). The quantity $\lambda_n(x)\text{Tr}[B^\dagger(x)A]$, defined as a pattern function, can be analytically evaluated, while the probability $p_n(x)$ must be determined experimentally. Notice that often (such as in the cases described in this paper) it is possible to obtain the whole quorum through a unitary operator $U(x)$ depending on the parameter $x$ acting on a single observable $O$, i.e.,

$$
C(x) = U^\dagger(x)OU(x).
$$

(4)

In this case, by calculating $\text{Tr}[C(x)\Psi]$ on a basis of eigenstates $|n\rangle$ of $O$, one finds that

$$
\langle A \rangle = \sum_n \int d\mu(x)p_n(x)\Omega_n \text{Tr}[B^\dagger(x)A],
$$

(5)

where here $p_n(x) = \langle n|U(x)\Omega U^\dagger(x)|n \rangle$ is the probability of obtaining the eigenvalue $\Omega_n$, when measuring the observable $O$ on the state $\Psi$ evolved by the unitary operator $U(x)$.

III. SU(1,1) TOMOGRAPHY

A. Tomography protocol

In this subsection we give the tomographic reconstruction procedure. Some simulated tomographic experiments are presented and discussed. The mathematical derivation of the reconstruction algorithm (7) will be postponed to the following subsection (Sec. III B). The system on which the procedure is to be applied is described in terms of the abstract operators of the su(1,1) algebra defined by Eq. (6). Its realization in practice can change completely from case to case, depending on the physical realization of the su(1,1) algebra. One then only has to substitute the appropriate system operators and measurement results in the formulas given here in order to obtain the reconstruction procedure suited to any particular system. For the sake of illustration, a couple of simple idealized physical systems are given at the end of the section.

The Lie algebra su(1,1) of the SU(1,1) group is spanned by the operators $K_+$, $K_-$, and $K_z$ which are defined by the commutation relations

$$
[K_+, K_-] = -2K_z, \quad [K_z, K_\pm] = \pm K_\pm,
$$

(6)

$$
K_z = \frac{i}{2}(K_+ + K_-), \quad K_\pm = \frac{i}{2}(K_+ - K_-).
$$

The Casimir invariant operator that labels all the unitary irreducible representations of the group is given by $(K_z)^2 - \frac{1}{2}(K_+^2 + K_-^2) = \kappa(\kappa - 1)$, where the eigenvalue $\kappa$ is also called the Bargmann index.

The general SU(1,1) tomographic identity corresponding to Eq. (5), for the reconstruction of the expectation value of the operator $A$ on an ensemble in the state $\Psi$, will be thoroughly derived in the following subsection. It is given by

$$
\langle A \rangle = \sum_{n,k} \int_0^{2\pi} d\varphi \int_0^\infty d\theta \text{tanh}(\theta) \langle j | e^{i(\theta/2)(\kappa \text{e}^{i\varphi}K_+ - \text{e}^{-i\varphi}K_-)} \Psi \rangle
$$

$$
\times e^{-i(\theta/2)(\kappa \text{e}^{i\varphi}K_+ - \text{e}^{-i\varphi}K_-)} |j\rangle
$$

$$
\times \text{Tr}[A \{(-1)^{j_k} \text{e}^{i\theta/2}(\text{e}^{i\varphi}K_+ - \text{e}^{-i\varphi}K_-), K_z \plus \kappa\}] (-1)^{\kappa + j},
$$

(7)

where $\{|j\rangle\}$ is the orthonormal basis of eigenvectors of $K_z$ corresponding to eigenvalue $\kappa + j$, and $\{\cdot, \cdot\}_+$ denotes the anticommutator. In Eq. (7) the quantity $\langle j | e^{i(\theta/2)(\kappa \text{e}^{i\varphi}K_+ - \text{e}^{-i\varphi}K_-)} \Psi \rangle e^{-i(\theta/2)(\kappa \text{e}^{i\varphi}K_+ - \text{e}^{-i\varphi}K_-)} |j\rangle$ is the probability distribution of the eigenvalue $j + \kappa$ obtained when measuring the observable $K_z$ on the input state $\Psi$ that has undergone an evolution described by the unitary operator

$$
U(\theta, \varphi) = e^{i(\theta/2)(\kappa \text{e}^{i\varphi}K_+ - \text{e}^{-i\varphi}K_-)}
$$

(8)

The experimenter must repeatedly measure the observable $K_z$ on different ensemble elements after evolving each of them with the unitary operator $U(\theta, \varphi)$, varying the parameters $\theta$ and $\varphi$ at each measurement. [As we will see in the following for the example of the electromagnetic field SU(1,1) reconstruction scheme, this amounts to measuring the number of photons after having squeezed the radiation for varying values of the squeezing amplitude and phase.]

In practice, the unbounded real amplitude $\theta \in [0, \infty)$ must be chosen randomly weighted with a cutoff distribution $p(\theta) = (1/l)\exp(-w\theta)\text{tanh}(\theta)$, where $w$ is a constant and $l$ is a normalization factor (an example is given in Fig. 1), while $\varphi$ can be chosen randomly in $[0, 2\pi]$ with uniform probabil-
ity. The parameters $\theta$ and $\varphi$ thus obtained are used to tune the experimental apparatus so that the input state is evolved by the operator $U(\theta, \varphi)$. Then the measurement of $K_z$ is performed, yielding the $i$th experimental result $m_i(\theta, \varphi)$ for $K_z = \kappa$. The expectation (7) is estimated through the average on $N$ measurements,

$$
\langle A \rangle = \frac{1}{N} \sum_{i=0}^{N} (-1)^{k+m_i(\theta, \varphi)} 2l \exp(w \theta_i) \\
\times \text{Tr}[A \{ (-1)^{K_z} e^{i\theta (e^{i\varphi}K_+ - e^{-i\varphi}K_-)} \} \rho_{nm}].
$$

(9)

where the function $l \exp(w \theta)$ is introduced in order to compensate the cutoff weighting. The parameter $w$ must be chosen sufficiently large to obtain a distribution of the squeezing amplitude $\theta$ in the allowed experimental range, and at the same time not too large, otherwise only too small $\theta$ values will result, and a too large number of experimental data would be needed for the tomographic reconstruction. Notice that any normalized decaying weight function can be used in place of the negative exponential used here.

In Figs. 2 and 3 we show some Monte Carlo simulations of the proposed method, where the measurement results $m_i(\theta, \varphi)$ have been simulated from the theoretical probability distribution of the input state evolved by $U(\theta, \varphi)$. The simulation of Fig. 2 refers to the state reconstruction of a system in a Perelomov coherent state [16] defined as

$$
|\alpha\rangle = \frac{(1-|\alpha|^2)^{\kappa}}{\sqrt{(2\kappa-1)!}} \sum_{n=0}^{\infty} \sqrt{(2\kappa-1+n)!} \frac{n!}{\alpha^n} |n\rangle.
$$

(10)

In Fig. 3 the simulation of the state reconstruction of an ensemble in the state $(|q\rangle + |r\rangle)/\sqrt{2}$, i.e., in a coherent superposition of two eigenstates of $K_z$, is given and a comparison is made between experiments carried out with different weight parameters $w$. Notice how, with the same number of data, a better reconstruction is performed with lower $w$, which corresponds to higher available squeezing amplitudes $\theta$.

The procedure that has been described is unbiased, since no systematic errors are introduced. Only statistical errors are present and can be made arbitrarily small by increasing the number of experimental data.

We now analyze two experimental setups in order to illustrate how, starting from the tomographic formulas given here, one may obtain the tomography suited to a particular system. They employ the SU(1,1) reconstruction formula (7) for the tomographic reconstruction of a two-mode radiation field and of a single-mode radiation field, respectively, and are based on parametric amplifiers and photodetectors. In this paper, ideal setups only are considered as examples of application of SU(1,1) tomography; an extensive analysis of nonunit quantum efficiency and more realistic setups will be considered in a subsequent paper.

The first setup is a two-mode setup, which employs the following realization of SU(1,1) through the radiation operators:

$$
K_+ \equiv a^\dagger b^\dagger, \quad K_- \equiv K_+^\dagger, \quad K_z \equiv \frac{1}{2}(a^\dagger a^\dagger b^\dagger b + 1),
$$

(11)

where $a$ and $b$ are the annihilation operators for the two radiation modes. The Casimir invariant operator is given by

$$
\frac{1}{4}(|a^\dagger a - b^\dagger b| + 1).
$$

The set $\{|j\rangle\}$ of eigenvectors of $K_z$ spans only the subspace of the two-mode Hilbert space in which the photon difference in the two modes is fixed and is given by $2\kappa - 1$. Thus, only the operators $A$ acting on this subspace can be reconstructed with such setup, and one can reconstruct the radiation state only if the difference between the photons in the two modes is fixed. Here $K_z$ is the observable "sum of photons" in the two modes and can be measured by two photodetectors. The operator $U(\theta, \varphi)$ describes a nondegenerate parametric amplifier (or phase insensitive amplifier), where $\theta$ and $\varphi$ are the squeezing amplitude and phase.
respectively, i.e., $U(\theta, \varphi) = \exp[\frac{i}{2}\theta(a^{\dagger}b^{\dagger}e^{i\varphi} - abe^{-i\varphi})]$. In Fig. 4 the block diagram for this experiment is presented.

The second setup, whose block diagram is given in Fig. 5, is a single-mode setup that employs the following SU$_{\sim}^{1,1}$ realization:

$$K_+ = \frac{1}{2}(a^{\dagger})^2, \quad K_- = K_+^{\dagger}, \quad K_z = \frac{1}{2}(a^{\dagger}a + 1),$$

where $a$ is the annihilation operator of the mode, and $\kappa = \frac{1}{4}, \frac{\pi}{2}$. Notice that this realization is actually a projective representation of SU$_{\sim}^{1,1}$. It allows one to reconstruct only the operators that act on the subspace of the radiation space constituted by the states with fixed (even or odd) parity in the number of photons. In this case, the observable $K_z$ is related to the number of photons in the mode, while the operator $U(\theta, \varphi)$ describes a degenerate parametric amplifier (or

FIG. 3. Comparison of identical simulated experiments for the measurement of the density matrix elements $\rho_{nm}$, carried out using different weight parameters $w$ in the probability distribution for the squeezing amplitude $\theta$. The system is in the state $|\psi\rangle = (|q\rangle + |r\rangle)/\sqrt{2}$, with $q=1$ and $r=6$. Here $\kappa=4/5$ and, as in the previous example, $2 \times 10^5$ measurements of $K_z$ divided into 20 statistical blocks have been simulated. (a) and (b) show the diagonal matrix elements with their theoretical values, and (c) and (d) show the absolute values of all matrix elements. The simulation in (a) and (c) is obtained with a weight $w=2.8$ (corresponding to $\theta$ varying in the interval $[0, \sim 1.2]$), while the simulation in (b) and (d) is obtained with $w=0.75$ (corresponding to $\theta$ varying in $[0, \sim 4]$).
with $\mathcal{N}=(2\kappa+m+n)^{-1}$.

We now show that the resolution of the identity of the form (2) based on the operators $C(\gamma)$ and $B(\gamma)$ defined in Eq. (14) follows from the orthogonality of some polynomials obtained from their matrix elements. These polynomials are defined by

$$
\langle m|e^{\gamma K_+ - \bar{\gamma} K_-}|n\rangle = \langle m|e^{iK_+} (1-|\xi|^2)K_+ e^{-iK_-}|n\rangle
= (-1)^m \xi^m (1-|\xi|^2) \sqrt{n!\Gamma(2\kappa+m)} \sqrt{m!\Gamma(2\kappa+n)}
\times S_{\kappa}^{(1,2\kappa-1,\ldots-m-n)}(|\xi|^2),
$$

(16)

where $\xi=(\gamma/|\gamma|) \tan \gamma$. The $n$-degree polynomial $S_{\kappa}^{(a,d)}(\rho)$ is given by

$$
S_{\kappa}^{(a,d)}(\rho) = \sum_k (-1)^k \frac{(a+n+d+k)!}{k! (k+d)!} \rho^k,
$$

(17)

where $k$ takes all the values such that the binomials are non-zero, i.e., $\max(0,-d) \leq k \leq n$. Notice that $S_{\kappa}^{(a,d)}(\rho)$ is a generalization of the Jacobi polynomials, since by using the property

$$
S_{\kappa}^{(a,m-n)}(\rho) = \rho^{n-m} \frac{m!\Gamma(\alpha+n+1)}{n!\Gamma(\alpha+m+1)} S_{\kappa}^{(a,m-n)}(\rho),
$$

(18)

we can write

\begin{align*}
S_{\kappa}^{(a,m-n)}(\rho) &= \begin{cases} 
p_{\kappa}^{(a,m-n)}(2\rho-1) & \text{for } m \geq n \\
p_{\kappa}^{(a,m-n)}(2\rho-1) \rho^{n-m} \frac{m!\Gamma(\alpha+n+1)}{n!\Gamma(\alpha+m+1)} & \text{for } m \leq n,
\end{cases}
\end{align*}

(19)

where $P_{\kappa}^{(a,\beta)}(x)$, with $\alpha>-1$ and $\beta>-1$, is the Jacobi polynomial of degree $n$ [17].

The orthogonality relation for the polynomials $S_{\kappa}^{(a,d)}(\rho)$ can be obtained either from the orthogonality relations of the Jacobi polynomials through Eq. (19) or from the necessary condition (22) for the orthogonal polynomials. Thus we obtain

$$
\frac{1}{\mathcal{N}} \int_0^1 d\rho (1-\rho)^{n} \rho^{d} S_{\kappa}^{(a,d)}(\rho) S_{\kappa}^{(a,d)}(\rho) = \delta_{n1},
$$

(20)

with the normalization

$$
\mathcal{N} = \frac{(n+d)!\Gamma(\alpha+n+1)}{n!\Gamma(\alpha+d+n+1)(\alpha+d+2n+1)}.
$$

(21)

Incidentally, notice that a useful recursion may be obtained from the necessary condition [17] for orthogonal polynomials, namely, a system of $n$-degree polynomials $p_n(\rho)$ satisfying the recursion.
with \( A_n, C_n \geq 0 \) is an orthogonal system. One can verify that the recursion (22) is satisfied for \( p_n(\rho) = \delta_n^{(\alpha_d)}(\rho) \), by choosing

\[
A_n = \frac{(\alpha + 2n + d + 1)(\alpha + 2n + d + 2)}{(n + 1)(\alpha + d + n + 1)},
\]

\[
B_n = \frac{\alpha(2n + d + 1)^2 + 2n(n + d + 1) + d^2}{(\alpha + d + n + 1)(n + 1)(\alpha + d + n + 2)},
\]

\[
C_n = \frac{(d + n)(n + \alpha)(\alpha + 2n + d + 2)}{(n + 1)(\alpha + n + d + 1)(\alpha + 2n + d)}.
\]

By making use of the above relations, we may derive the orthogonality condition (2) for SU(1,1). In fact, we see that

\[
\frac{1}{N} \int_{\mathbb{C}} \frac{d^2 \gamma \tanh|\gamma|}{|\gamma|} \langle \gamma | e^{\gamma K_+ - \gamma K_-} | n \rangle \langle n | e^{-\gamma K_+ + \gamma K_-} | k \rangle
\]

\[
= (-1)^{n+l} \sqrt{\frac{n!\Gamma(\alpha + m + 1)\Gamma(\alpha + l + 1)}{m!\Gamma(\alpha + n + 1)\Gamma(\alpha + k + 1)}} \int_{\mathbb{C}} \frac{d^2 \xi}{\pi} (1 - |\xi|^2)^{n-1} S_n^{(\alpha,m-n)}(\xi^2) S_{n-l-k}^{(\alpha,l-k)}(\xi^2)
\]

\[
= \frac{(-1)^{n+l}}{2\pi N} \sqrt{\frac{n!\Gamma(\alpha + m + 1)\Gamma(\alpha + l + 1)}{m!\Gamma(\alpha + n + 1)\Gamma(\alpha + k + 1)}} \int_{\mathbb{C}} \frac{d^2 \phi}{\pi} e^{i\phi(m-n+l-k)} \int_{\mathbb{C}} \frac{d\rho}{\rho} (1 - \rho)^{\alpha} \rho^{(m-n+k-l)/2} S_n^{(\alpha,m-n)}(\rho) S_{n-l-k}^{(\alpha,k-l)}(\rho)
\]

\[
= \delta_{mk} \delta_{nl},
\]

with \( \alpha = 2\kappa - 1 \), \( \zeta = (\gamma/|\gamma|) \tanh|\gamma| \), \( \gamma = \rho \tanh e^{i\varphi} \), and

\[
N = \frac{n!\Gamma(\alpha + m + 1)\Gamma(\alpha + l + 1)}{m!\Gamma(\alpha + n + 1)\Gamma(\alpha + k + 1)},
\]

and where the double integral on \( d^2 \zeta \) is to be performed on the unit circle. Equation (26) guarantees the existence of a tomographic identity of the form (1), with \( B(\gamma) \) and \( C(\gamma) \) given by Eq. (14).

Using the identity resolution (26), we can now obtain the SU(1,1) tomographic reconstruction procedure as given in Eq. (3), namely,

\[
\langle A \rangle = \int_{\mathbb{C}} \frac{d^2 \gamma \tanh|\gamma|}{|\gamma|} \text{Tr}[AB(\gamma)] \text{Tr}[C(\gamma)],
\]

where \( \mathcal{G} \) is the system density matrix and \( A \) is an arbitrary system operator.

How can this identity be used to obtain the SU(1,1) tomography? The obvious way to obtain a reconstruction procedure of the form (3) would be to devise a measurement procedure for the Hermitian operator \( i(\gamma K_+ - \gamma K_-) \). However, an apparatus to measure such observables is unreliable. It would be much better to measure the operator \( K_z \), which, as we have shown, is obtained both in the single-mode and in the two-mode systems through photodetection. We will now show how the tomographic identity we found can be employed, requiring the measurement of \( K_z \) on a state that has been evolved by the unitary operator \( \exp(\gamma K_+ - \gamma K_-) \), i.e., we use a reconstruction procedure of the form (5). For example, in the single-mode and two-mode realizations given above, this resorts to squeezing the input state and then performing a photodetection. [Of course, in any physical situation in which \( i(\gamma K_+ - \gamma K_-) \) is easily measurable, then Eq. (28) can be directly employed for the SU(1,1) tomography.]

To this end, let us regard \( K_x, K_y, \) and \( K_z \) as elements of \( \text{su}(1,1) \), that is, as \( 2 \times 2 \) complex matrices, and the exponential map \( \exp \) as a function from \( \text{su}(1,1) \) to \( \text{SU}(1,1) \). In doing so,

\[
K_x = -\frac{i}{2} \sigma_3, \quad K_y = -\frac{i}{2} \sigma_2, \quad K_z = \frac{1}{2} \sigma_3,
\]

where \( \sigma_i \) are the Pauli matrices. Denote \( \vec{K} = (K_x, K_y, K_z) \), \( \vec{n} = (\sin \theta \cos \varphi, \sin \theta \sin \varphi, \cosh \theta) \), and \( \vec{n}_z = (\sin \varphi, -\cosh \varphi, 0) \); then one can easily check that

\[
\exp[2i(\vec{b} \cdot K)](-1)^{K_z} = (-1)^i \vec{a} \cdot \vec{K}
\]

\[
= \exp(-i \theta \vec{n}_z \cdot \vec{K}) (-1)^{K_z} \exp(i \theta \vec{n}_z \cdot \vec{K}),
\]

for all \( \gamma = a + ib = \theta e^{i(\varphi - \psi)} \) in the complex plane.

Let \( U \) be the unitary representation of SU(1,1) with Bargmann index \( \kappa \). As a consequence of the Stone theorem,
One has $e^{i\gamma s U_{\exp \eta K_s} = U_{\exp \eta K_s}}$, with $s = x, y, z$, and $C(\gamma) = U_{\exp \{ibK_s + aK_s\}}$, where, with slight abuse of notation, we denote by the same symbol $K_s$ both the $2 \times 2$ matrix and the self-adjoint operator acting on the Hilbert space of the system. Hence, since Eqs. (30) and (31) hold at group level and $U$ is a representation, one has

$$\text{Tr}[C(\gamma)(-1)^{K_s\sigma}] = \sum_{j=0}^{\infty} \langle j | e^{i\theta_{\alpha_{\beta}} \cdot \hat{K}} e^{-i\theta_{\alpha_{\beta}} \cdot \hat{K}} | j \rangle \times (-1)^{j+\kappa},$$

(32)

where $\langle j | e^{i\theta_{\alpha_{\beta}} \cdot \hat{K}} e^{-i\theta_{\alpha_{\beta}} \cdot \hat{K}} | j \rangle$ is the probability of obtaining the result $j + \kappa$, when measuring the operator $K_s$ on the input state $\sigma$ evolved by the unitary operator $U_\theta = e^{i\theta_{\alpha_{\beta}} \cdot \hat{K}}$, i.e., the state $e^{i\theta_{\alpha_{\beta}} \cdot \hat{K}} e^{-i\theta_{\alpha_{\beta}} \cdot \hat{K}}$.

Moreover, it is immediately clear that the orthogonality relation (26) is valid also if we take, in place of $C(\gamma)$ and $B(\gamma)$, the operators $C'(\gamma)$ and $B'(\gamma)$ defined as

$$C'(\gamma) = e^{i\gamma K_s \cdot \sigma K_s}(\-1)^{K_s\sigma},$$

$$B'(\gamma) = \{C'(\gamma), K_s\}^+_\sigma.$$

Thus, rewriting the tomographic identity (28) with $C'(\gamma)$ and $B'(\gamma)$, and using Eq. (32), we find the SU(1,1) tomography reconstruction procedure, i.e.,

$$A = \frac{1}{\pi} \sum_{j=0}^{\infty} \int_0^{2\pi} d\varphi \int_0^{\infty} d\theta \tanh(\theta) \langle j | e^{i\theta_{\alpha_{\beta}} \cdot \hat{K}} e^{-i\theta_{\alpha_{\beta}} \cdot \hat{K}} | j \rangle \times \text{Tr}[AB^{\dagger}(\theta, \varphi)](-1)^{j+\kappa},$$

(34)

from which Eq. (7) follows immediately.

IV. CONCLUSIONS

In this paper we have introduced, derived, and numerically tested a quantum tomographic reconstruction procedure based on SU(1,1) symmetry. The tomographic algorithm has been derived using the general method of Refs. [13,14], and the orthogonality relation of the SU(1,1) tomography turns out to be a generalization of the Jacobi polynomial orthogonality identity. The method has been tested on a set of computer simulated experiments, corresponding to the reconstruction of different quantum states. Excellent agreement between theoretical and experimental simulated matrix elements was found, within perfectly unbiased statistical errors. Two examples of physical systems to illustrate this reconstruction procedure were given: the setups are based on the SU(1,1) symmetry of parametric amplification of two-mode and single-mode electromagnetic fields.
